Brief Communication

THE DIAGNOSTIC VALUE OF PLASMA SELENIUM ESTIMATIONS ON BLOOD SAMPLES COLLECTED IN CONJUNCTION WITH EXSANGUINATION OF SWINE*

It has been shown that the validity of certain clinical-biochemical blood values may change immediately post mortem (Jönsson & Pehrson 1968, Simesen & Storm 1973). The aim of this investigation was to establish whether selenium estimations on blood samples collected at slaughter are of diagnostic value.

Material and methods

The material consisted of preslaughter blood samples from 22 experimental swine with plasma selenium values varying from 0.015 to 0.105 p.p.m. (wet weight) (Table 1) and samples from the same animals taken in conjunction with the exsanguination following electric stunning. All samples were coded and unidentifiable by the person who performed the analyses.

The selenium content was estimated according to the fluorometric procedure described by Olson (1969).

Results and discussion

The results of all analyses of the samples are shown in Table 1. The av. value for plasma selenium content in the blood taken before slaughter was 0.059 and 0.065 in the plasma sample taken in conjunction with exsanguination. When comparing (paired t-test) the level in individual swine before and at exsanguination a significant difference was found (P < 0.02). The two sets of data are linearly correlated, y = 0.0049 + 1.0241 x, where x and y are the pre- and postslaughter values, respectively.

Jönsson & Pehrson have pointed out that samples collected at exsanguination generally appear to be subject to greater errors than can be explained by the errors in the analytical methods.

Table 1. Comparison of plasma Se values before slaughter and during exsanguination.

An increase in plasma selenium content at exsanguination has — as far as we know — not been reported before. The increase is so great, however, (av. 10 %) that under certain circumstances it could invalidate the diagnostic value of selenium determination in plasma collected in conjunction with slaughter. Therefore the preslaughter values should be calculated using the equation given above. Generally we have found plasma or serum selenium estimations to be a very responsive indicator of the selenium status of an animal.
